

Untitled 8

FlexBox

Flexbox is a way to prepare and arrange elements in your html layout. You can align elements in a particular direction, distribute them in a space, and decide spacing between the elements.

Easy to get start with

Easy to manage

More readable

And Widely accepted

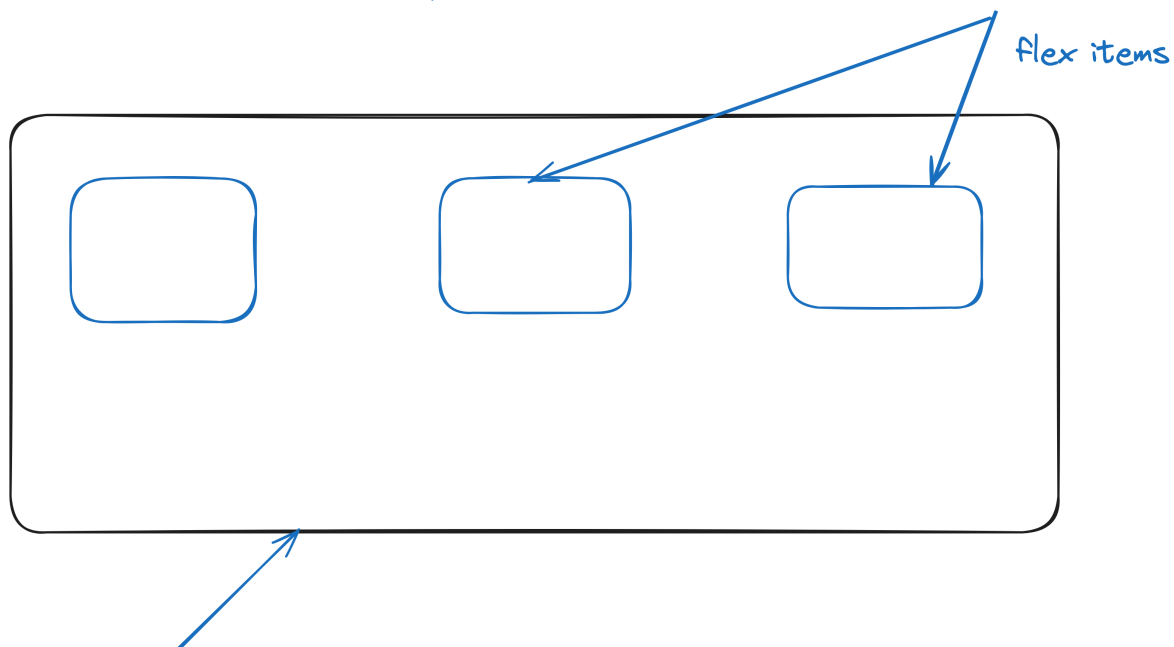

Flex box terminologies

1. Container - Flexbox container

The flexbox container is the element on which we can activate flex property, and then control the children using flex. Flex container is the parent that contains flex items.

2. Flex items

Flex items are the elements present inside the flex container.

Flex container - display: flex;

3. Flex axis and flex direction

Each flex container has a direction associated to it. The items inside the container are always arranged in that direction only. The default direction is row but we can change it to column.

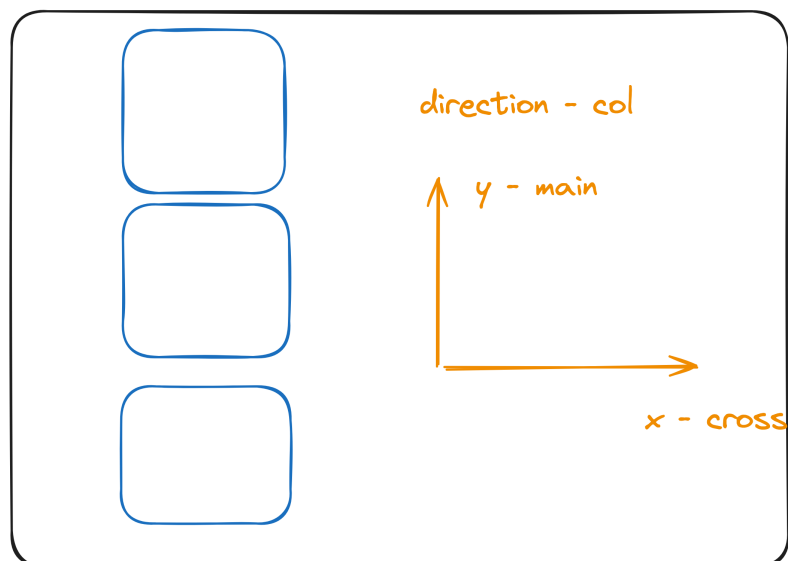

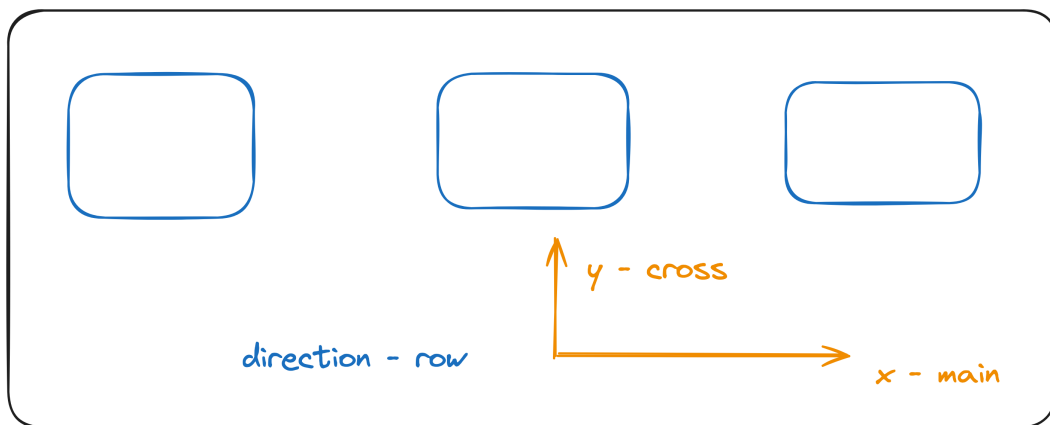

Based on the direction we have two axis defined in the container

If the direction is row, then x-axis is the *MAIN* axis and y-axis is the cross axis.

If the direction is col, then y-axis is the *MAIN* axis and x-axis is the cross axis.

MAIN - primary axis

CROSS - secondary axis

they are added on css rules of container

TO handle distribution on main axis we use - justify-content property

TO handle distribution on cross axis we use - align-items property

Flex Direction -> This property specifies the direction of the flex items inside the flex container

- row
- column
- row-reverse
- column-reverse

Flex wrap -> This property allows flex items to wrap in multiple lines.

Justify-content -> This property helps us to align and distribute elements across the main axis

Align Content- This property controls the alignment of flex lines when there is extra space in the cross axis
